### **Author contributions**

DLD, STW, KGT, CAV and EKS conceived, designed and acquired the funding for the study. PK wrote the manuscript and performed the analyses. JDM and ATK provided the statistical supervision and contributed to the analyses. All coauthors contributed to writing and reviewing and approved the final version of the manuscript.

### **Funding**

US National Institutes of Health grants: P01 HL132825, K25 HL136846, P01 HL105339, P01 HL114501, R21 HL107927, R01 HL097144

### **Declaration of interests**

STW has received royalties from UpToDate. EKS received grant and travel support from GlaxoSmithKline. DLD, PK, JDM, ATK, CAV and KGT report no conflict of interest.

## **Abstract**

Chronic Obstructive Pulmonary Disease (COPD) likely has developmental origins, however the underlying molecular mechanisms are not fully identified. Investigation of lung tissue-specific epigenetic modifications such as DNA methylation using network approaches might facilitate insights linking in-utero smoke (IUS) exposure and risk for COPD in adulthood.

We performed genome-wide methylation profiling for adult lung DNA from 160 surgical samples and 78 fetal lung DNA samples isolated from discarded tissue from 8-18 weeks of gestation. Co-methylation networks were constructed to identify preserved modules that shared methylation patterns in fetal and adult lung tissues and associations with fetal IUS exposure, gestational age and COPD.

Weighted correlation networks highlighted preserved and co-methylated modules for both fetal and adult lung data associated with fetal IUS-exposure, COPD and lower adult lung function. These modules were significantly enriched for genes involved in embryonic organ development and specific inflammation-related pathways including Hippo, PI3K/AKT, Wnt, MAP-Kinase and TGF-beta signaling. Gestational age-associated modules were remarkably preserved for COPD and lung function and were also annotated to genes enriched for the Wnt and PI3K/AKT pathways.

Epigenetic network perturbations in fetal lung tissue exposed to IUS and of early lung development recapitulated in adult lung tissue from former smokers with COPD. Overlapping fetal and adult lung tissue network modules highlighted putative disease pathways supportive of exposure-related and age-associated developmental origins of COPD.

## **Introduction**

COPD remains a major cause of mortality worldwide [1–3] and is caused by genetic and epigenetic risk factors [4, 5] that communicate through biological networks. Early life factors associated with reduced maximally attained lung function [6] and accelerated lung function decline [5] might predispose to adult lung diseases such as COPD [7–9]. Investigating these factors has become a greater focus [10], as these insights may impact diagnostic, therapeutic and preventative interventions. Maternal smoking during pregnancy is prevalent, at 14-26% in the US population [11–13] and 10-35% worldwide [12, 14]. This poses severe risks to the developing fetus and fetal lung [15] including intrauterine growth abnormalities [16, 17], preterm birth [18], low birth weight [19] and altered immune responses [20, 21]. DNA methylation has been suggested as a potential mediator between maternal smoking and low birth weight [22]. A longitudinal study [23] identified persistently perturbed methylation marks associated with maternal smoking during pregnancy. While detrimental effects of parental smoke exposure on early-life development [24] and its associations with bronchopulmonary dysplasia [25] are widely recognized, links to asthma [26] and adult chronic diseases including COPD have been emerging more recently [27–32]. There is also evidence that maternal smoking is a risk factor for severe, early-onset COPD [33]. A recent epigenome-wide meta-analysis [34] identified more than 6,000 significant differentially methylated (DM) CpG sites (CpGs) in cord blood associated with maternal smoking and lung developmental processes [34]. A recent meta-analysis of 1,688 children in five cohorts identified differentially methylated regions in cord blood DNA, associated with lower lung function in newborns and asthma and COPD in later life [35].

Identifying early COPD and associated mechanisms is crucial for an improved understanding of lung disease pathophysiology and defining therapies [36]. DNA methylation represents a molecular mark that is critical for pre- and post-natal lung development but perturbable by in-utero exposures [37]. Such perturbations may set the fetal lung on a trajectory of altered development and risk for adult lung diseases including COPD. Experimental data suggests that

DNA methylation changes are dynamic and tissue-specific during early development [38]. However, there are limited studies in lung tissue investigating epigenetic links to the developmental origins of COPD. Network approaches can be used to cluster complex biological processes most relevant for age-related respiratory diseases [39, 40]. In this study, we hypothesize that epigenetic signatures of IUS exposure and age in fetal lung tissue are associated with COPD and lung function in adult lung tissue and would highlight functionally relevant co-methylation modules supportive of the developmental origins of adult lung disease.

## Methods

### Study Samples

The fetal lung DNA samples were isolated from discarded tissue from 8-18 weeks of gestation at pseudoglandular and early canalicular stages of human lung development as previously described [41]. Approval was obtained from the Partners Human Research Committee Institutional Review Board in Boston, MA.

Genome-wide methylation assays were performed using 750 ng of bisulfite-treated DNA per sample using the Infinium HumanMethylation450 BeadChip array (Illumina, San Diego, CA) [42] and further data processing was performed using Minfi [43]. Details on sample dropout and filtering of CpGs are described in Supplementary Table 1. Details on ancestry composition estimates [53] and adjustment for confounding using BACON [54] are included in the supplement. Since the fetal lung tissue samples are de-identified, data were only available for gestational age, fetal sex, and cotinine levels. Sex was determined using unique Y chromosome microarray probes as previously described [44] and verified using X chromosome methylation. IUS exposure was inferred by measuring placental cotinine concentrations. Exposure was treated as both a continuous and dichotomous predictor variable, with levels of cotinine  $\leq 7.5$  ng/g considered as unexposed (control group) and levels of cotinine  $> 7.5$  ng/g as exposed; this level has been reported to have a high sensitivity and specificity for smoke exposure during pregnancy [41]. Further details are available elsewhere [45]. We used our previously published [46] adult lung tissue methylation results (from the Lung Tissue COPD study (LT-COPD), n=160, 114 cases and 46 healthy smoker controls) to replicate the fetal lung dataset findings.

### Network approach: Weighted Gene Correlation Network Analysis (WGCNA)

An overview of the analytical pipeline is represented in **Figure 1**. For fetal lung data, methylation was the dependent variable (outcome) and IUS-exposure was the predictor. Quality control, preprocessing (Supplementary Table 1) and differential methylation analyses for fetal lung data

were performed prior to performing network analyses to make it suitable for comparison to the adult lung tissue site-specific CpG analysis [46] and have been detailed in Supplementary Methods. We further performed an independent network co-methylation analysis in both tissues. The filtered and post-processed 349,355 CpGs from the fetal lung data were evaluated for overlap with the quality controlled CpGs from the LT-COPD study. The overlapping set of 349,325 CpGs from both the fetal lung (reference) and the adult LT-COPD (test) datasets were retained for identifying co-methylated modules (clusters of correlated CpGs) and their associations with phenotypic traits using Weighted Correlation Network Analysis (WGCNA) [47]. Modules are named based on associated numbers and colors as output from WGCNA. Phenotype variables including age, forced expiratory volume in the 1<sup>st</sup> second (FEV<sub>1</sub>), forced vital capacity (FVC), FEV<sub>1</sub>/FVC ratio, quantitative markers of emphysema (LAA950, perc15), time since quitting smoking (months) and pack-years (quantitative measure for smoking intensity) were analyzed as continuous except sex, IUS exposure status (1/0 with 1=exposed) and COPD status (1/0 with 1=COPD cases) for investigating module-trait associations. Module Membership (MM) quantifies the contribution of each CpG in the module and allows screening for disease-related hub CpGs/genes. We also evaluated module preservation between fetal and adult lung datasets defined by  $Z_{\text{summary}}$  as a measure of connectivity of CpGs within co-methylated modules. As a sensitivity analysis, we used LT-COPD dataset as the starting reference and repeated the above analyses to assess whether the LT-COPD associated modules for COPD, lung function and age recapitulate in fetal lung tissue. Our workflow for the network analysis using WGCNA is shown in **Figure 1**. Detailed methods and used parameters for reproducibility of the network analysis are described in the supplementary methods.

### **Enrichment and Pathway analysis**

The R packages missMethyl [48, 49] and gprofileR [50] were used to perform enrichment analysis for the differentially methylated CpGs and the annotated genes respectively.

EnrichmentMap [51] in Cytoscape 3.6.1 was used to create a network representation of the biological processes enriched in the modules of interest (FDR<0.05), using the gProfiler output including transcription factors, gene ontology terms, Reactome and KEGG pathways.

### **Integration with prior gene expression and GWAS associations**

In line with our hypothesis to identify fetal origins of COPD, we investigated all CpGs with a Module Membership of 0.70 or greater and with gene annotations for correlations with the previously published COPD differential expression in the LT-COPD dataset [46] and with 82 published COPD genome-wide associations (GWAS) [52].

## **Results**

### **1. Support for the fetal origins of COPD using network methods**

Our study included 78 fetal lung (42 IUS-exposed and 36 unexposed) samples and 349,355 CpGs that passed the quality control (QC) measures (Supplementary Table 1); of those, 349,325 CpGs overlapped with the LT-COPD dataset. We first evaluated the 535 significant differentially methylated CpG-COPD associations (FDR < 5% and difference in mean methylation > 1%) published from our LT-COPD study [46] and investigated their methylation patterns in the fetal lung EWAS findings (Suppl. Fig. 1-4, Supplementary Tables 2-4). Overlapping CpGs highlighted robust overlap for genes (Permutation based p-value =  $9.9 \times 10^{-4}$ , Suppl. Fig. 5) including *CHRM1*. *CHRM1* had the highest methylation difference in the LT-COPD dataset (cg06289725: FDR:  $1.81 \times 10^{-6}$ ; 10% hyper-methylated in COPD cases) and nominal significance and same direction of effect in the fetal lung data with a relative hypermethylation of 1.9% in smoke-exposed compared to unexposed fetal lung samples (Suppl. Fig. 6, detailed in Supplementary results).

## 2. IUS Exposure-COPD associations and preserved modules

We performed an independent network analysis using WGCNA for the overlapping set of 349,325 CpGs from the fetal lung methylation data and identified 319,366 CpGs assigned to 103 co-methylation modules (Suppl. Fig. 7A). A brief framework for selecting preserved module-trait associations between fetal and adult lung datasets, focusing on lung tissue modules with high network preservation is highlighted in **Table 1**.

We identified seven modules: ME90:darkolivegreen, ME49:darkseagreen, ME97:indianred3, ME46:mediumpurple3, ME100:skyblue, ME34:purple and ME6:plum1 associated with (nominal  $P \leq 0.05$ , **Figure 2A**, Suppl. Tab. 5) either measure of IUS-exposure (binary or continuous). ME46:mediumpurple3, ME100:skyblue and ME34:purple were associated with both measures of exposure (**Figure 2A**). Projecting the fetal lung module structure as reference on to the adult lung tissue methylation data (Suppl. Fig. 7B), we observed that these IUS exposure modules identified in fetal lung associate with either COPD or with FEV<sub>1</sub> and FEV<sub>1</sub>/FVC ratio in adult lung tissue subjects (**Figure 2B**). The ME100:skyblue module had a relatively suggestive association for COPD, but they all remained significant for FEV<sub>1</sub> at FDR <0.05 (**Figure 2B**, Suppl. Tab. 6). Based on  $Z_{\text{summary}}$ , three of the seven exposure modules: ME34:purple, ME90:darkolivegreen, ME100:skyblue were highly preserved and ME46:mediumpurple3 was moderately preserved between both fetal lung and COPD datasets that we refer to as exposure-COPD modules (**Table 1**, Suppl. Fig. 8, Suppl. Tab. 7). Consistent with the associations, eigengene values of the ME90:darkolivegreen module were relatively increased and positively correlated with higher cotinine values in IUS-exposed compared to unexposed fetal lung samples (Suppl. Fig. 9A-B). Largest positive eigengene values of the ME90:darkolivegreen module were driven by lower FEV<sub>1</sub> values in COPD adults compared to controls with pack-years pointing towards more recent smoking cessation (Suppl. Fig. 9C-E). For ME34:purple and ME100:skyblue modules, eigengene values were significantly correlated with IUS-exposed subjects in fetal lung dataset and lower FEV<sub>1</sub> in LT-COPD dataset (Suppl. Fig. 10-11). Based on the Module Membership (MM) criteria,

*FOXB1* (MM=0.881), *TSSK6* (MM=0.804), and *SLC26A8* (MM=0.871) were the top genes in the ME34:purple, ME90:darkolivegreen and ME100:skyblue modules respectively (Suppl. Tab. 8).

### **3. Fetal age-COPD modules suggestive of developmental perturbations**

Eighteen modules were associated with fetal age but not cotinine exposure (Suppl. Fig. 7A, FDR<0.05, Suppl. Tab. 5). Fifteen of those were associated with COPD in adult lung tissue (Suppl. Fig. 7B, Suppl. Tab. 6). Most of the fetal age associated modules were also associated with lung function phenotypes (FEV<sub>1</sub> and FEV<sub>1</sub>/FVC ratio; Suppl. Tab. 6). Based on  $Z_{\text{summary}}$ , the highly preserved age-associated modules (**Figure 2A-B**) included: ME13:orange, ME79:salmon, ME30:black, ME4:yellow and ME18:saddlebrown with ME46:mediumpurple3 as moderately preserved (**Table 1**, Suppl. Fig. 8, Suppl. Tab. 7). The highest preserved ME13:orange module also had a suggestive association with quantitative CT measures of emphysema (LAA950, P=0.075, **Figure 2B**). Based on the MM criteria, *PRDM8* (MM=0.91), *ZNF704* (MM=0.92), *PCOLCE* (MM=0.92), *RNF213* (MM=0.96) and *HNF1A* (MM=0.79) are the top genes annotated to CpGs in the ME79:salmon, ME13:orange, ME30:black, ME4:yellow and ME18:saddlebrown modules respectively (Suppl. Tab. 9).

### **4. Module connecting exposure and fetal development to COPD**

The ME46:mediumpurple3 module showed moderate preservation (Suppl. Tab. 7), and its association with cotinine exposure and age in fetal lung (nominal P<0.05, Suppl. Tab. 5), and COPD and all lung function phenotypes in the LT-COPD dataset (**Figure 2**, Table 1) made it an interesting module to study further. The associations with fetal age and COPD, FEV<sub>1</sub> and FEV<sub>1</sub>/FVC ratio in LT-COPD dataset remained significant at FDR<0.05 (Suppl. Tab. 6).

Consistent with those associations, the ME46:mediumpurple3 module was strongly associated with IUS-exposure and the methylation levels of this module were overall 1.4% higher among IUS-exposed compared to unexposed fetal lung samples (**Figure 3A**). Moreover, smoke exposed

samples having high cotinine levels were positively correlated with the ME46:mediumpurple3 module eigengene ( $R=0.30$ ,  $P=8.4 \times 10^{-3}$ , **Figure 3B**). Notably, the methylation levels were also overall 1.1% higher in COPD cases (**Figure 3C**) and this positive eigengene association was correlated with lower FEV<sub>1</sub> values ( $R=-0.32$ ,  $P=1.0 \times 10^{-4}$ , **Figure 3D**); but not associated with cigarette smoke exposure/pack-years ( $R=0.09$ ,  $P=0.22$ , **Figure 3E**). Based on the MM criteria, *HARS2* (MM=0.79) and *GUK1* (MM=0.79) were the top genes in the ME46:mediumpurple3 module (Suppl. Tab. 8). Seven significant hyper-methylated CpGs were annotated to the TSS of multi-site gene *STK19* within the module (Suppl. Fig. 12).

### **5. Enrichment and Pathway analysis**

Among the preserved and IUS-exposure-COPD or lung function associated modules, the ME34:purple module was enriched in several developmental processes and pathways including Hippo, Wnt, MAPK (mitogen-activated protein kinase) and TGF- $\beta$  (transforming growth factor beta) signaling as well as several transcription factors (Suppl. Tab. 10). The ME90:darkolivegreen module (Suppl. Fig. 13) was primarily associated with positive regulation of telomerase RNA localization to Cajal body (Suppl. Tab. 11). The ME100:skyblue module (Suppl. Fig. 14, Suppl. Tab. 11) was enriched for cell-cell communication and *ERBB4* signaling with members of the Hippo pathway and cadherin gene family. Fetal age-COPD associated modules (ME79:salmon, ME13:orange, ME30:black, ME4:yellow and ME18:saddlebrown) were mostly large and demonstrated significant enrichment (Suppl. Tab. 12-16, Suppl. Fig. 15) related to development, proliferation, differentiation and morphogenesis. Significantly enriched pathways included regulation of the PI3K/AKT (phosphatidylinositol 3-kinase/Protein Kinase B) network, ERBB and Wnt signaling, signaling by receptor tyrosine kinases and MAPK. Interestingly, most inter-connected and enriched terms in the ME13:orange module included Wnt signaling and the PI3K/AKT signaling network (Suppl. Tab. 15, **Figure 4**). The ME46:mediumpurple3 module (Suppl. Tab. 11, Suppl. Fig. 16) was enriched for viral pathways

(FDR adjusted  $P = 6.58 \times 10^{-7}$ ), ribonucleoprotein biogenesis (FDR adjusted  $P = 4.09 \times 10^{-5}$ ), DNA repair (FDR adjusted  $P = 8.44 \times 10^{-4}$ ) and the PI3K/AKT signaling (FDR adjusted  $P = 1.81 \times 10^{-3}$ ).

### **6. Adult lung network projection onto fetal lung methylation**

To assess the robustness of our findings, we repeated our analyses using the overlapping set of 349,325 CpGs from the adult LT-COPD dataset projecting the adult lung methylation network structure as the starting reference on the fetal lung methylation data (test) and identified 55 co-methylation modules (Suppl. Fig. 17-18, Suppl. Tab. 17). Most modules were associated with fetal age, lung function and COPD but none significantly associated with both IUS-exposure and COPD. Enriched pathways for those modules included EGFR tyrosine kinase inhibitor resistance, ERBB signaling down-regulation and PI3K/AKT. This analysis further supports that adult lung network perturbations might recapitulate and have origins in fetal development associated epigenetic perturbations, especially with enrichment in the PI3K/AKT signaling pathway.

### **7. Integration with prior gene expression and GWAS associations**

We identified 14,236 CpGs at an MM sub-threshold of 0.70 or greater annotated to 7,364 unique genes across all modules (Suppl. Tab. 18). Of those, 100 CpGs from the ME34:purple, ME79:salmon, ME30:black, ME13:orange and ME4:yellow modules mapped to 62 unique differentially expressed genes ( $FDR < 0.05$ ) in the LT-COPD dataset. The highest MM was associated with the CpG site: cg07495027 mapped to *EDNRB* gene in the ME4:yellow module (Suppl. Tab. 18). The strongest correlation between CpG methylation and gene expression was observed for *EEF1B2* ( $cor = -0.42$ ,  $P = 9.9 \times 10^{-8}$ ) and *ABL1* ( $cor = 0.34$ ,  $P = 2.4 \times 10^{-5}$ ) genes. Interestingly, 38 unique high MM genes had an overlap with the 82 previously identified COPD-GWAS associations (Suppl. Tab. 18). Several genes were also shared between modules with maximum presence for *ASAP2*, *IER3* and *THRA* across modules.

## Discussion

Network analyses may reveal deeper insights into the developmental origins of disease. Addressing the fetal origins hypothesis, we utilized a network driven approach to focus on smaller gene clusters in relevant functional pathways that may influence risk for adult COPD. The network analysis suggested that the early origins of COPD may be related to both the developmental and exposure related perturbations in gene networks, not single genes working in isolation.

Pathway analysis of IUS-exposure, fetal age and COPD-associated module genes (ME46:mediumpurple3) as well as the most highly preserved module genes (ME13:orange) included annotation to the PI3K pathway. The PI3K/AKT pathway not only plays crucial role in human disease [55] but also represents a therapeutic target for aging [56], lung dysfunction, asthma pathogenesis [57] and treatment of COPD [58]. Most of the mentioned Hippo pathway components interact, including *Mst1/2*, *Sav1*, *Lats1/2*, *Mob1* or *Yap*. Their homozygous deletion causes embryonic lethality [59, 60]. The Hippo signaling pathway regulates lung development/alveolarization [61, 62] and closely interacts with TGF- $\beta$  [63], Wnt, Notch and Hedgehog signaling pathways. Furthermore, the Hippo pathway is implicated in progression of lung diseases including asthma and COPD [64, 65], and may therefore be a crucial link for fetal origins of COPD. The Wnt pathway is annotated to almost all of the highlighted modules. Wnt/ $\beta$ -catenin is known for its critical role in embryonic and fetal lung development [66]. IUS-exposure has been reported to be associated with down-regulation of genes in Wnt signaling and impaired lung growth in the developing fetus [67]. We have previously identified Wnt signaling genes associated with lower lung function in asthmatics [68]. The Wnt-beta catenin pathway has also been implicated in COPD [69–71] and is regulated by *FAM13A*, a COPD susceptibility gene [72]. These findings further support that the disruption of the Wnt pathway in early life may be a prominent contributor to fetal origins of COPD. The role for Wnt in lung aging has been

proposed [73] suggesting this pathway together with the PI3K/AKT pathway may link fetal exposure and adult lung disease through perturbations in aging pathways. Highlighted modules revealed pathways to consider for further investigation for fetal origins of COPD. Genes with the highest module membership may represent functional COPD susceptibility hubs perturbed in early life. *FOXBI*, the gene with highest MM in the ME34:purple module is a transcription factor that has been implicated in embryonic development and was associated with childhood asthma symptoms in a genome-wide association study in Latin American children [74]. The ME34:purple module included multiple enriched pathways (Hippo, PI3K, MAPK, Wnt, TFG- $\beta$ ). ME90:darkolivegreen module enriched in positive regulation of telomerase activity catalyzed by telomerase reverse transcriptase (hTERT) enzyme has often been linked to chromosome maintenance [75][76]. Its negative association with pack-years and sex may point to sex-specific activation of repair mechanisms after smoking cessation. The ME100:skyblue module was enriched for several members of the cadherin family implicated in lung diseases such as asthma [77] and COPD [78]. *ERBB4* signaling highlighted through the ME100:skyblue module included the *YAPI* gene, a component of the Hippo pathway [60]. *ERBB4* deletion is associated with delayed fetal development [79]. *ERBB4* demonstrated increased gene expression in smokers to smokers with COPD and inverse association with FEV<sub>1</sub>, suggesting links to COPD severity [80]. Integration with previously reported gene expression and GWAS associations highlighted candidate genes such as *EDNRB* and *IER3*. Increased *EDNRB* expression has been associated with emphysema, FEV<sub>1</sub>/FVC [81] and COPD severity [82]. The *IER3* knockout in mouse models was associated with immune dysfunction and interference with several pathways including PI3K/AKT [83].

The biologically plausible and statistically significant pathways we identified using correlation networks is a contrast to the limited findings of the single CpG site analysis. Our findings of many differentially methylated CpGs with small magnitude of effect is consistent though with previously published large epigenome-wide studies associated with maternal smoking [84].

Notably, the gamma-aminobutyric acid (GABA) and adenosine receptor signaling pathways were identified from overlapping fetal and adult lung EWAS results. Nicotine exposure has been reported previously to increase GABA signaling in airway epithelium [85], while adenosine receptors are known for their anti-inflammatory properties and therapeutic potential for the treatment of asthma and COPD [86].

A key strength of the study includes interrogating epigenetic profiles in the fetal lung tissue ascertained during airway branching morphogenesis. These samples are particularly relevant to test the developmental origins of COPD hypothesis. Abnormalities in bronchial airways during this stage can lead to decreased airflow and slowed growth of airways, limiting maximally attained lung function. Analytical strengths of our study include methylation profiles in both fetal and adult lung tissue using the same platform and leveraging a network-based approach for both relevant tissues. Due to complex underlying mechanisms, it remains a challenge to identify significant single site associations while retaining statistical power, often with effect sizes of small magnitude which is consistent with previously published large epigenome-wide studies [84]. Previous studies have identified and compared differentially methylated CpGs associated with COPD in whole blood and lung tissue. In light of the considerable heterogeneity across studies and varying statistical analyses [87], our systematic evaluation of previously validated COPD EWAS associations found in blood [46, 88–90] did not identify any consistent overlap with our high module membership CpGs.

We have therefore provided extensive details about the network modules to facilitate future research and collaboration in this less explored area. We acknowledge that our study has several limitations including the sample sizes of the datasets and the use of lung homogenates. Moreover, prospective studies with expanded coverage of methylation sites such as from the Illumina EPIC array and bisulfite sequencing may support validation and improve our understanding of the identified associations significantly. Further, dichotomizing continuous variables such as cotinine facilitates interpretation and is consistent with IUS exposure as measured in many studies.

However this may lead to loss of information especially with small datasets. Therefore, to be consistent with the literature but also to more precisely model exposure, we reported module-trait associations using both dichotomous and continuous measures of cotinine. In addition, we have limited phenotype data associated with the fetal lung samples. To address this, we directly measured cotinine and given the timing of sample collection presumed elevated cotinine is related to maternal smoking and not nicotine replacement therapy or e-cigarette use. Efforts linking fetal tissue findings with cord blood will increase the opportunity to fully leverage cord blood datasets and understand fetal origins of adult lung disease. Future research to understand the developmental contributions to COPD should focus on single cell analyses to further understand fetal programming in the lung relevant to adult tissue.

## **Conclusion**

In summary, our co-methylation network evaluation resulted in the identification of gene modules linking fetal lung tissue IUS-exposure and fetal age to adult lung function and COPD. Additional studies and functional validation will support causal links between fetal methylation alterations in pathways including Hippo, Wnt and PI3K/AKT and risk for and development of COPD. As we move towards precision medicine, understanding the impact of early life molecular trajectories will provide unprecedented insight into complex adult lung diseases and reveal ways to leverage the plasticity of the epigenome towards primordial prevention, lung health and resilience despite early life programming.

**Table 1.** Preserved module associations with IUS-exposure, COPD/lung function and age with annotated pathways. The table highlights module: A. associations with exposure in fetal lung and COPD/lung function in LT-COPD dataset B. associations with age in both datasets and COPD/lung function in LT-COPD dataset. A preservation score as defined by the default WGCNA criteria<sup>44</sup> was used to assess the density and connectivity patterns between CpGs in a module.  $2 < Z_{summary} < 10$  implies weak to moderate preservation and  $Z_{summary} > 10$  implies strong and high preservation. Additionally, modules with preservation score as:  $6 < Z_{summary} < 10$  were considered moderately preserved. Only high or moderately preserved modules were included in this table and the scores are rounded without decimal places. Genes in the highlighted pathways for each module are detailed in Suppl. Tab. 19.

Footnotes:

‡ Modules associated with both exposure and age in fetal lung and COPD/lung function and age in adult lung tissue dataset

\* Modules associated with age in both fetal lung and adult lung tissue datasets

X denotes no association with the variable

Abbreviations: Chronic Obstructive Pulmonary Disease (COPD), Forced Expiratory Volume in 1 second ( $FEV_1$ ), Forced Vital Capacity (FVC); Mitogen-activated protein kinase (MAP-Kinase), Transforming growth factor beta ( $TGF-\beta$ ), phosphatidylinositol 3-kinase/Protein Kinase B (PI3K/AKT), Epidermal growth factor receptor (EGFR), BMP (bone morphogenetic protein), GABA (gamma aminobutyric acid),  $IFN-\gamma$  (interferon-gamma-mediated), TLR (toll-like receptor), small nuclear ribonucleoproteins (snRNPs), small Cajal body-specific RNPs (scaRNPs), small nucleolar RNPs (snoRNPs)

**A. Preserved and exposure-COPD/lung function associated modules**

Modules	CpGs	Fetal Lung associations		LT-COPD associations	Preservation (score)	Pathways (number of annotated genes)	Genes with highest MM
		Binary	Continuous				
ME34:Purple,	5,024	Yes	Yes	FEV <sub>1</sub>	High (18)	Hippo (44), Wnt (89), MAP-Kinase (13), protein serine/threonine kinase (69) and TGF-beta (41) pathways	<i>FOXB1</i>
ME90:Darkolivegreen	543	X	Yes	Sex, FEV <sub>1</sub> , FVC	High (15)	snRNP, scaRNP, snoRNP and telomerase biogenesis (4)	<i>TSSK6</i>
ME100:Skyblue	712	Yes	Yes	FEV <sub>1</sub> , FVC, FEV <sub>1</sub> /FVC	High (10)	ERBB4 (5) and cell-cell signaling (10)	<i>SLC26A8</i>

**B. Preserved and age\*-COPD/lung function associated modules**

ME13:Orange	878	X	X	COPD, FEV <sub>1</sub> , FVC, FEV <sub>1</sub> /FVC, monthsquit	High (36)	Wnt signaling (23), PI3K/AKT (19) and MAP-Kinase (17) network	<i>ZNF704</i>
ME79:Salmon	3,348	X	X	COPD, FEV <sub>1</sub> , FVC, FEV <sub>1</sub> /FVC, monthsquit	High (35)	Protein serine/threonine kinase (44), Wnt (53), phosphatidylinositol 3-kinase (16), ERBB (21), TGF-beta (23) and BMP (24) signaling pathways	<i>PRDM8</i>
ME30:Black	10,135	X	X	COPD, FEV <sub>1</sub> , FVC, FEV <sub>1</sub> /FVC	High (18)	Protein serine/threonine kinase signaling (83), Wnt signaling (133), BMP (45), phosphatidylinositol 3-kinase (38) and GABA (9) signaling pathways	<i>PCOLCE</i>
ME4:Yellow	29,032	X	X	COPD, FEV <sub>1</sub> , FVC, FEV <sub>1</sub> /FVC, monthsquit	High (16)	ERBB (94), PI3K/AKT (66), Wnt (191), EGFR (74), Protein serine/threonine kinase (150), TGF-beta (91) and IFN- $\gamma$ (50) signaling pathways	<i>RNF213</i>
ME18:Saddlebrown	682	X	X	COPD, FEV <sub>1</sub> , FVC, FEV <sub>1</sub> /FVC	High (13)	Trans-synaptic and synaptic signaling	<i>HNF1A</i>

**C. Exposure and Age-COPD/lung function associated and preserved modules**

ME46:Mediumpurple3 <sup>†*</sup>	284	Yes	Yes	COPD, FEV <sub>1</sub> , FVC, FEV <sub>1</sub> /FVC	Moderate (7)	RNP biogenesis (11), PI3K/AKT (8), MHC-mediation (8), signaling by WNT (5), ER-phagosome (4), MAP-Kinase (6) signaling pathways	<i>HARS2</i> , <i>GUK1</i>

## Figure legends with figures

**Figure 1.** Overview of the study flowchart and analytical pipeline for preprocessing and module network creation using WGCNA. ME90:darkolivegreen, ME46:mediumpurple3, ME100:skyblue, ME34:purple, ME79:salmon, ME13:orange, ME30:black, ME4:yellow and ME18:saddlebrown correspond to the resulting modules from WGCNA output (ME: module eigengene).

The colors in boxes represent different stages of analytical pipeline. Green, gray and pink colors correspond to the steps for data pre-processing, downstream post-processing and overlap of fetal and adult lung tissue single site CpG analysis respectively. Orange and light-blue arrows point to the modules and associated findings resulting from fetal lung and adult lung as reference networks respectively.

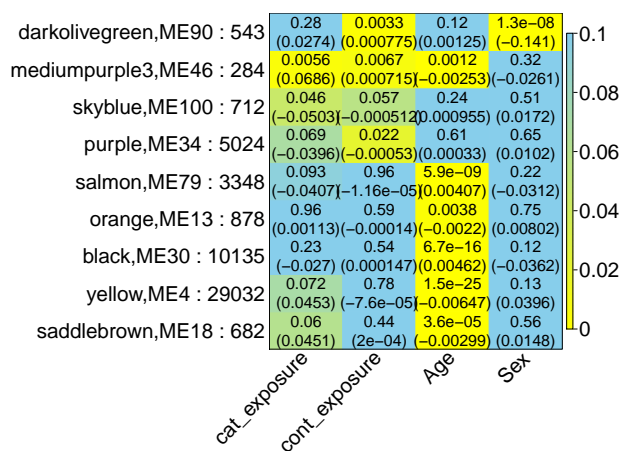

**Figure 2.** Module-trait association heat-maps for the selected nine exposure and age modules associated with COPD and lung function phenotypes highlighting fetal origins for COPD at network level. **A.** Association of modules in the fetal lung network with the traits of interest in the fetal lung data. **B.** Association of LT-COPD dataset traits of interest projected on to fetal lung module network as reference. The Y-axis shows the modules labels (number:color), followed by the number of CpGs in that respective module. The panels highlight modules associated with IUS-exposure, gestational age, COPD and lung function phenotypes. The blue and yellow colors in the boxes represent the scale for significance (nominal P<0.05) with blue being not significant and yellow being highly significant. The mean beta effect estimate per module corresponding to the trait is shown below in parentheses.

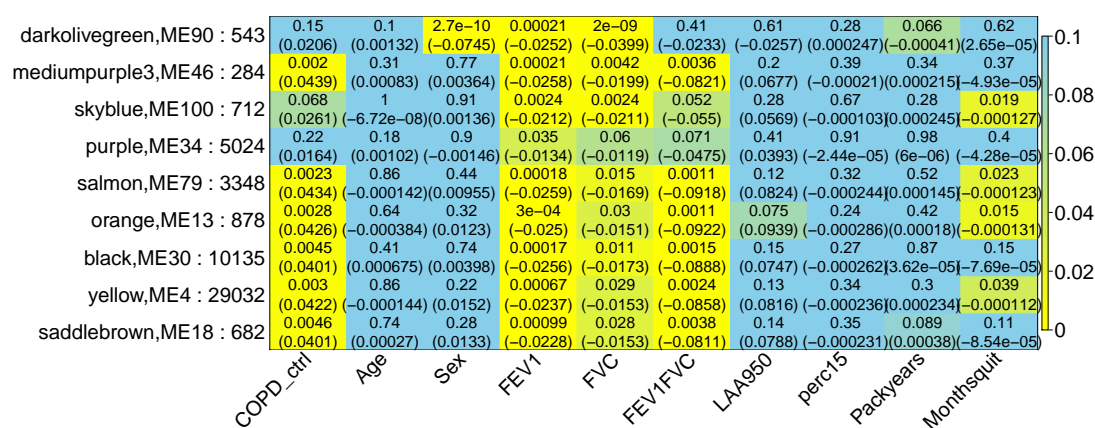

Abbreviations: cat\_exposure: IUS-exposure (exposed versus unexposed), cont\_exposure: IUS-exposure (continuous cotinine variable). COPD\_ctrl: COPD (cases versus controls), FEV<sub>1</sub>: forced expiratory volume in 1 sec, FVC: forced vital capacity, FEV<sub>1</sub>/FVC ratio, LAA950: quantitative emphysema, perc15 and monthsquit: months since quitting smoking

Missing Data: FEV<sub>1</sub> and FVC were missing for 13 subjects, LAA950 and perc15 were missing for 55 subjects and monthsquit was missing for one subject. Subjects with missing data were removed prior to running models for these predictors.

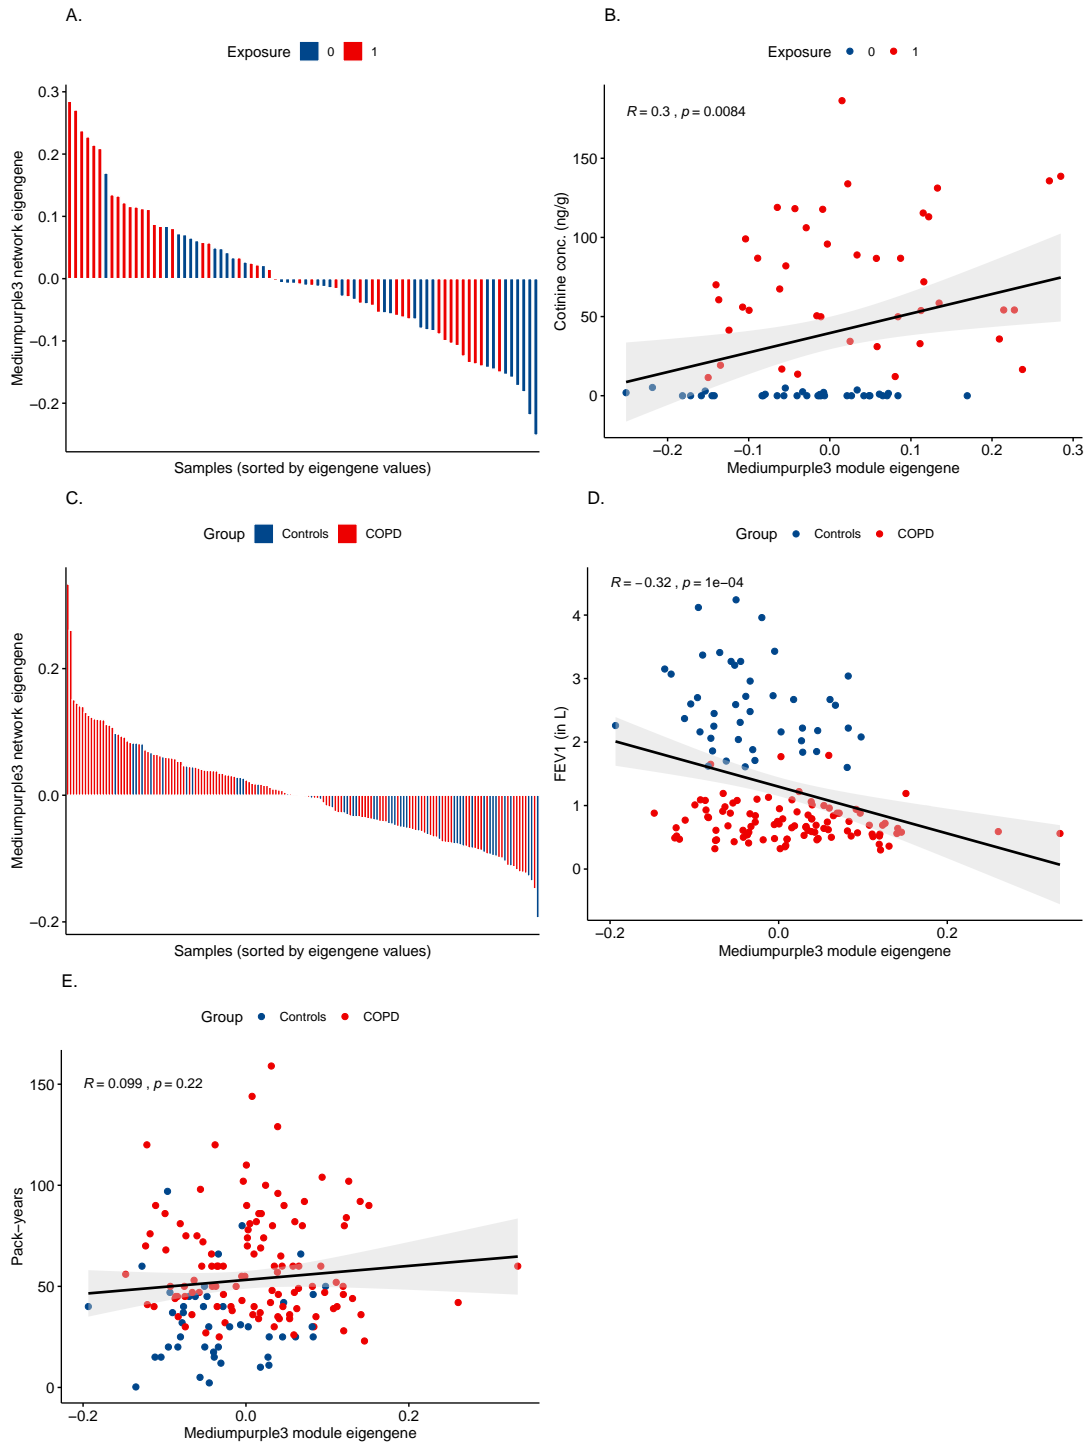

A.

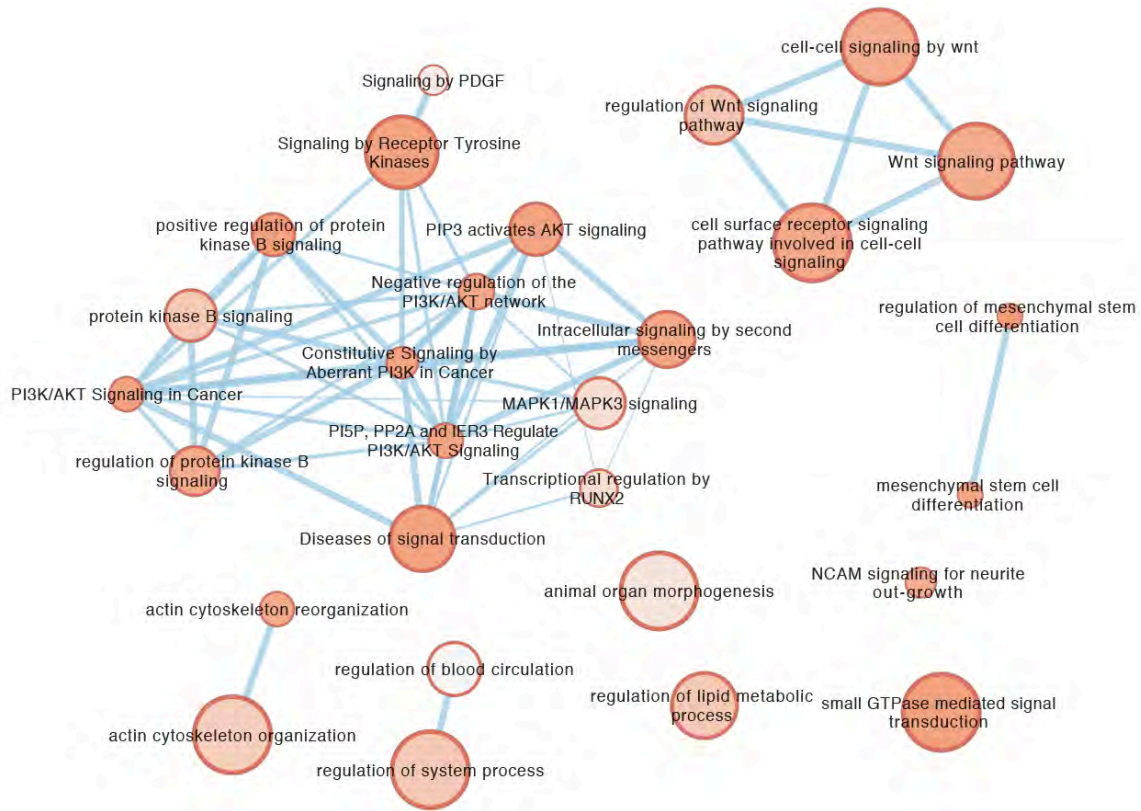

B.

**Figure 3.** Correlation plots between the ME46:mediumpurple3 methylation eigengene and traits of interest. A. Eigengene values of the ME46:mediumpurple3 module were robustly increased and B. associated with higher cotinine values in IUS-exposed fetal lung samples compared to unexposed samples. For exposure, 0 corresponds to unexposed samples whereas 1 corresponds to IUS-exposed samples C. Eigengene values of the ME46:mediumpurple3 module were robustly increased and D. significantly correlated with lower FEV<sub>1</sub> values in COPD adults compared to smoker controls E. but not associated with cigarette smoke intensity (pack-years).

**Figure 4.** Reactome analysis reveals PI3K/AKT and Wnt signaling pathway networks for the ME13:orange module (FDR<0.05). Node size corresponds to the significant number of genes in the enriched term (Suppl. Tab. 15, supplement). Node color corresponds to the significance of the term. Edge thickness corresponds to the number of genes that overlap between two connected terms/gene-sets.

51

52 **Methods**

53

54 Adult Lung tissue samples were collected from individuals undergoing thoracic or lung volume  
55 reduction surgery. All subjects were former smokers categorized as COPD cases or controls  
56 based on pre-surgical spirometry. Institutional Review Board approval was obtained at three  
57 medical centers: Brigham and Women's Hospital (Boston, MA), St. Elizabeth's Hospital (Boston,  
58 MA), and Temple University Hospital (Philadelphia, PA); all subjects provided written informed  
59 consent.

60

61 *Quality control and preprocessing of fetal lung samples*

62 Percent methylation is reported as the Illumina  $\beta$ -value for each CpG site, which is the ratio  
63 between methylated signal intensity and total probe signal intensity and corresponds to a  
64 continuous value between 0 and 1. Data import, Normal-exponential using out-of-band probes [2]  
65 (noob) normalization for background correction and preprocessing was performed using the  
66 Bioconductor package Minfi [3]. Percent methylation values were further subjected to within-  
67 array normalization for type2 probe bias correction using the Beta Mixture Quantile  
68 normalization (BMIQ - watermelon version 1.25.1) method [4]. As part of the quality control  
69 (QC), we removed probes with low detection pvalues (cut off 0.05), X and Y chromosome  
70 probes, non-CpG probes (CH probes), probes containing SNPs at the CpG interrogation or at the  
71 single nucleotide extension and polymorphic or cross-reactive probes [5]. Probes for CpG sites  
72 likely to be influenced by and within zero to one base of a known SNP were also excluded  
73 (dbSNP 141 GRCh37.p13). Duplicate checking using SNP concordance based on the 65 rs probes  
74 identified one duplicate sample that was removed. A comparison between predicted and  
75 phenotype sex based on probes mapped to only X and Y chromosomes using MDS  
76 (multidimensional scaling) plot identified 12 likely sex mismatches that were excluded from  
77 further analysis. Clustering was performed using constrained analysis of principal coordinates

78 (CAP) using R package vegan [6]. Details of the summary statistics for the QC process are  
79 mentioned in Suppl. Tab. 1.

80 Ancestry composition for fetal lung dataset was estimated from genetic data using TRACE  
81 program (fast and Robust Ancestry Coordinate Estimation) as implemented in the LASER  
82 package [7]. Of the 78 fetal lung samples, 75 samples existed in the genetic data, therefore this  
83 analysis further led to removal of 3 samples. We adjusted using the first three principal  
84 components (PCs) which explained most variability in the data (12.4%) and then accounted for  
85 bias due to unknown confounders using R package BACON [8]. Additionally, as a sensitivity  
86 analysis, we adjusted our module-trait associations (modules identified using WGCNA) using the  
87 first three PCs for the 75 fetal lung samples.

88

#### 89 *Statistical differential methylation analyses*

90 For fetal lung data, methylation was the dependent variable (outcome) and IUS-exposure was the  
91 predictor. Compared to our previously published epigenome-wide association study (EWAS) [9],  
92 herein we optimized and updated the methods for sample quality control and computational  
93 pipelines for the fetal lung data to make it suitable for comparison to the adult lung tissue site-  
94 specific CpG analysis [1] and for an independent network co-methylation analysis in both tissues.  
95 Site based differential methylation analysis for fetal lung samples was performed using linear  
96 regression models as a part of Bioconductor package limma (version 3.37.7) [10] adjusting for  
97 age, sex, sample plate, and sentrix position. Differentially methylated (DM) sites were  
98 categorized as relatively hyper- or hypo-methylated if they showed higher or lower percent  
99 methylation in smoke-exposed compared to unexposed fetal lung samples respectively and were  
100 considered nominally significant at a p-value cut off of 0.05. CpG sites (CpGs) were mapped to  
101 genes using Human Genome build: GRCh37/hg19 annotation. Genes were classified as multi-site  
102 if multiple associated CpGs mapped to that gene.

103 We additionally performed a permutation test to evaluate whether the observed overlap with the  
104 significant findings of the LT-COPD study [1] (n=535 CpGs) in the same direction of effect  
105 (hyper- or hypo-methylated in both the fetal lung dataset and the LT-COPD study) was larger  
106 than expected by chance. Five hundred thirty five CpGs were randomly selected from the fetal  
107 lung association data and investigated for overlap with the 535 CpGs identified in the LT-COPD  
108 study. This process was repeated 1000 times to estimate the mean number of overlapping CpGs,  
109 providing the empirical p-value estimated as the number of permutations with an overlap larger or  
110 equal than the observed overlap, divided by the total number of permutations.

111

112 *Network approach: Weighted Gene Co-expression Analysis (WGCNA)*

113 We used a blockSize of 40,000 to cluster CpGs. Signed networks were built with a soft  
114 thresholding power of 5. Separate co-methylation networks/modules corresponding to clusters of  
115 CpGs were constructed for both fetal and adult lung methylation by means of hierarchical  
116 clustering. Highly correlated module CpGs are represented and summarized by their first  
117 principal component referred to as the module eigengene [11]. Module Membership (MM),  
118 ranging from 0 to 1, quantifies how contributory a CpG is to a given module [12]. This allows  
119 screening for disease-related intramodular hub CpGs and the associated genes [12]. Multivariate  
120 regression models were subsequently employed using limma for both the fetal and the adult lung  
121 datasets to evaluate module eigengene-phenotype associations (to identify relationships between  
122 modules and clinical variables). Module preservation was evaluated using the R package  
123 WGCNA (version 1.63) [13]. After investigating module-trait associations in fetal lung, using  
124 adult lung methylation data, we projected the module structure of the reference fetal lung network  
125 on to the LT-COPD methylation matrix to evaluate the same set of module CpGs and co-  
126 methylation relationships and their associations to the phenotypes in both datasets. In this  
127 analysis, phenotype variables were analyzed as continuous except sex, IUS exposure status (1/0  
128 with 1=exposed) and COPD status (1/0 with 1=COPD cases). In the fetal lung dataset, we

129 additionally evaluated module associations with cotinine as a continuous phenotype. All module-  
130 trait associations in the main text have been reported at nominal  $P < 0.05$  while the FDR-adjusted  
131 P-values have been included in the Supplementary Tables 5 and 6.

132 We also evaluated the Zsummary [14] as a measure of module preservation after permutation of  
133 module assignment using the original fetal lung WGCNA network. We followed the default  
134 WGCNA criteria [14] for the output:  $Z_{\text{summary}} < 2$  implies no preservation,  $2 < Z_{\text{summary}} < 10$   
135 implies weak to moderate preservation and  $Z_{\text{summary}} > 10$  implies strong and high preservation.  
136 Module preservation is used to assess whether the density and connectivity patterns of modules  
137 defined in the fetal lung data as the reference set were also preserved in the original com-  
138 methylation of the LT-COPD test set.

139 In addition, as a sensitivity analysis, we used COPD as the starting reference, performed the same  
140 analyses to assess whether the LT-COPD associated modules for COPD, lung function and age  
141 recapitulate in fetal lung tissue.

142

## 143 **Results**

### 144 *Global and Differential methylation in fetal lung*

145 DNA methylation data was analyzed for fetal lung tissue for 42 IUS-exposed (53.84%) and 36  
146 unexposed samples (46.15%). Preprocessing and filtering resulted in 349,355 quality controlled  
147 CpG sites that were used for further analysis. Of those, 349,325 CpGs overlapped with the LT-  
148 COPD set retained for network analysis. The overall mean methylation difference between  
149 smoke-exposed vs. unexposed samples based on all 349,355 CpGs was 0.00039 (95% CI: -0.001,  
150 0.002;  $p=0.68$ ), however the variance between both groups was statistically different (95% CI:  
151 0.986, 0.999,  $p=0.03$ ). Constrained analysis of principal coordinates showed that exposure was  
152 significantly associated with methylation outcome (nominal  $p=0.03$ ). The samples showed a clear  
153 clustering by exposure after constraining covariates (Suppl. Fig. 1A-B). There were relatively  
154 more hyper- ( $n=6,969$ ) than hypo-methylated ( $n=3,180$ ) CpGs (Suppl. Fig. 2A). Between  
155 unexposed and IUS-exposed fetal lung samples, 10,149 CpGs (2.90%) annotated to 5,176 unique  
156 genes were nominally statistically significant at  $P<0.05$  (Suppl. Tab. 2) and were distributed  
157 evenly across all autosomal chromosomes (Suppl. Fig. 2B). None of the CpGs remained  
158 significant after correction for multiple testing (Suppl. Fig. 2B). Out of those, 6,315 CpGs had  
159 CGI annotations, which were significantly enriched in North shelves (2%,  $P=8.4\times 10^{-3}$ ), North  
160 shores (2.67%,  $9.6\times 10^{-27}$ ) and South shores (2.47%,  $P=8.3\times 10^{-10}$ ) against the CpGs on the 450K-  
161 array platform (Suppl. Fig. 4). Filtering the data using a methylation difference ( $\beta$ -diff) cut off of  
162 at least 1% between exposed and unexposed samples resulted in 6,520 CpGs and a cut off of 5%  
163 resulted in 230 CpGs (part of Suppl. Tab. 2). While investigating multi-CpG site genes, *PTPRN2*  
164 ( $n=20$ ) and *GSTT1* ( $n=6$ ) were annotated with maximum CpGs at a cut-off of 1% and 5%  
165 difference in methylation respectively. One of our previously validated genes [9] *DPP10* was also  
166 a part of 5% beta difference list annotated to five CpGs. Twenty-four of the 10,149 CpGs  
167 annotated to 10 genes (*JAK2*, *GSTT1*, *ZNF714*, *LOC391322*, *TRIM10*, *KNDC1*, *UNC93B1*,

168 *GSTM1*, *SMYD3*, *MYT1L*) showed an absolute methylation difference ranging from around 10-  
169 15%. Among these, some genes were annotated to more than one CpG site such as *GSTT1* (n=6,  
170 all hyper-methylated), *TRIM10* (n=5, hyper-methylated; n=1 hypo-methylated) and *ZNF714*  
171 (n=2, all hypo-methylated) (Suppl. Tab. 2).

172

### 173 ***Ancestry composition estimation in fetal lung data***

174 Our fetal lung study samples overlap with reference samples from each of the five 1000 Genomes  
175 super-populations (African, Ad-Mixed American, East Asian, European, and South Asian; Suppl.  
176 Fig. 3A). Adjusting with PCs and applying BACON did not significantly change our EWAS  
177 associations (Suppl. Fig. 3B; results remained nominal. Considering this update did not alter our  
178 findings, we kept the original analysis unchanged. After adding PCs to the models for identifying  
179 the module-trait associations, the original findings in Figure 2 were attenuated to some extent,  
180 however stayed robust and did not alter the overall conclusion.

181

### 182 ***Differentially methylated CpGs from adult lung study assessed in fetal lung***

183 The top five annotated CpGs based on significance in the LT-COPD dataset and having the same  
184 direction of effect in the fetal lung dataset (hypo- or hyper-methylated in both datasets) included  
185 *GLT1D1*: cg25823837, *C10orf11*: cg08754149, *PITPNM1*: cg01748627 and *CHRM1*:  
186 cg06289725. Based on the significance threshold in both datasets ( $P < 0.05$  in fetal lung and FDR  
187 in LT-COPD dataset, Suppl. Tab. 3), we identified 12 CpGs annotated to 10 genes of which seven  
188 had the same direction of effect (*GRM1*: cg06121352, *PPMIN*: cg05260085, *SPOP*:  
189 cg22160463, *ANO8*: cg03665970, *CHRM1*: cg06289725; cg07980854, cg22209918;  
190 Hypergeometric P-value for the observed overlap of seven CpGs= $1.8 \times 10^{-7}$ ).

191 Overall, 255 of the 535 LT-COPD CpGs showed a consistent direction of effect (irrespective of  
192 P-value threshold in the fetal lung dataset) in the fetal smoke exposure EWAS that were subjected

193 to enrichment analysis; of which 213 showed relative hyper-methylation in smoke-exposed fetal  
194 lung and COPD cases. (Suppl. Tab. 3, Permutation based p-value =  $9.9 \times 10^{-4}$ , Suppl. Fig. 4).  
195 The top pathway GO terms (GO: 0007214, GO:0001973) for these 255 CpGs were enriched in  
196 gamma-aminobutyric acid signaling (*GNAI2*, *GABRA* family genes: *GABRA5*, *GABBR2*), and  
197 adenosine receptor signaling (*P2RY1*) pathways (Suppl. Tab. 4).  
198 Among the top hits, *CHRM1* had the highest methylation difference in LT-COPD dataset  
199 (cg06289725: FDR:  $1.81 \times 10^{-6}$ ; 10% hyper-methylated in COPD cases) and nominal significance  
200 and same direction of effect in the fetal lung data with a relative hypermethylation of 1.9% in  
201 smoke-exposed compared to unexposed fetal lung samples (Suppl. Tab. 3). Fifteen CpGs were  
202 annotated to *CHRM1* in fetal lung data (Suppl. Fig. 6), of which two CpGs: cg00987015  
203 (chromosome 11:62,688,751,  $p=9.0 \times 10^{-3}$ ), cg06289725 (chromosome 11:62,689,081,  $p=0.029$ )  
204 located in 5'UTR and transcription start site (TSS) respectively (Suppl. Tab. 2, Suppl. Fig. 6A),  
205 were nominally associated. The latter was also promoter flanking and strongly enriched in  
206 regulatory region of DNase hypersensitivity sites (DHS) (Suppl. Fig. 6B).

207

### 208 ***Enrichment and Pathway analysis for IUS Exposure-COPD modules***

209 Gene enrichment and pathway analysis was performed individually for each of the preserved and  
210 IUS-exposure-COPD or lung function associated modules (ME90:darkolivegreen,  
211 ME46:mediumpurple3, ME34:purple and ME100:skyblue). Among those, ME34:purple was the  
212 largest and enriched in several developmental and cellular processes (FDR < 0.05; Suppl. Tab.  
213 10) such as embryonic organ development and morphogenesis, response to oxygen levels, cell  
214 cycle, apoptosis, signal transduction, cellular senescence and pathways including Hippo, Wnt,  
215 MAP-Kinase (mitogen-activated protein kinase) and TGF- $\beta$  (transforming growth factor beta)  
216 signaling (Suppl. Tab. 10). Some of the developmental, smoke-related or lung function associated  
217 genes that are part of the ME34:purple module (Suppl. Tab. 10) include: *IGFBP2-BP3* (enriched  
218 terms: cell signaling, WNT pathway, apoptosis), *HHIP* (enriched terms: skeletal system

219 morphogenesis), *PITX2* (enriched terms: head/brain development), *PIK3CD* (enriched terms:  
220 neuron morphogenesis), *SHH* (enriched terms: nervous system/brain/embryonic development),  
221 and *CELSR3* (enriched terms: tissue morphogenesis). The top biological processes in the  
222 ME34:purple module included RNA polymerase II regulatory region DNA binding (FDR  
223 adjusted  $P = 9.51 \times 10^{-12}$ ), head development (FDR adjusted  $P = 1.57 \times 10^{-7}$ ) and central nervous  
224 system development (FDR adjusted  $P = 5.86 \times 10^{-6}$ ) that were annotated to several transcription  
225 factors such as *PAX6*, *RUNX3*, *TBX5*, *TBX20* and genes such as *GATA5*, *ESR1*, *EGR1*, *VDR*,  
226 *CTCF*, *CRISPLD2*, *SHH*, *ERBB4*; and several of the WNT family genes such as *WNT2*, *WNT3*,  
227 and *WNT5A*. The ME90:darkolivegreen module (Suppl. Fig. 13) was primarily associated with  
228 positive regulation of telomerase RNA localization to Cajal body (Suppl. Tab. 11, FDR adjusted  
229  $P=0.03$ ) and was enriched in four genes: *CCT4*, *NAF1*, *NHP2* and *CCT3*. The ME100:skyblue  
230 module (Suppl. Fig. 14) was enriched for only Reactome pathways (Suppl. Tab. 11) including  
231 cell-cell communication (10 genes, FDR adjusted  $P = 9.45 \times 10^{-3}$ ), cell junction organization (8  
232 genes, FDR adjusted  $P = 0.01$ ), *ERBB4* signaling (5 genes, FDR adjusted  $P = 0.04$ ). The cadherin  
233 gene family (*CDH1*, *CDH4*, *CDH12*, *CDH13*, *CDH15*) was highly enriched in cell-cell  
234 communication and cell-junction interactions associated with the ME100:skyblue module.

235

### 236 ***Enrichment and Pathway analysis for fetal age-COPD modules***

237 Fetal age-COPD associated modules (ME79:salmon, ME13:orange, ME30:black, ME4:yellow  
238 and ME18:saddlebrown) demonstrated significant enrichment. Most of the biological processes  
239 enriched in the ME79:salmon module (FDR  $<0.05$ ) included terms related to development,  
240 proliferation, differentiation and morphogenesis. The top biological process in the ME79:salmon  
241 module was enriched for organ morphogenesis (FDR adjusted  $P = 1.12 \times 10^{-20}$ ), followed by  
242 skeletal system (FDR adjusted  $P = 1.29 \times 10^{-17}$ ) and embryo development (FDR adjusted  $P =$   
243  $1.85 \times 10^{-14}$ ) and included genes such as *IGF1*, *WNT16*, *PROM1*, *PAX6*, and *TFAP2B*, all  
244 important components of transmembrane receptor protein serine/threonine kinase signaling

245 pathway, and the Wnt signaling pathway (Suppl. Tab. 12). Developmental biological processes  
246 and pathways also dominated the larger ME30:black and ME4:yellow modules. The top  
247 biological process in the ME30:black module was enriched for organ morphogenesis (FDR  
248 adjusted  $P = 6.45 \times 10^{-28}$ ) followed by embryo development (FDR adjusted  $P = 1.08 \times 10^{-18}$ ) and the  
249 top genes included *WNT16* (also a part of the Wnt signaling pathway – GO:0016055, FDR  
250 adjusted  $P = 2.54 \times 10^{-12}$ , Suppl. Tab. 13). The top enriched biological process in ME4:yellow  
251 module was for cytoskeleton organization (FDR adjusted  $P = 1.43 \times 10^{-12}$ ) and included pathways  
252 such as ERBB signaling (FDR adjusted  $P = 3.45 \times 10^{-7}$ ), Wnt signaling (FDR adjusted  $P =$   
253  $2.67 \times 10^{-5}$ ), signaling by receptor tyrosine kinases (FDR adjusted  $P = 7.36 \times 10^{-6}$ ) and MAPK  
254 signaling (FDR adjusted  $P = 2.56 \times 10^{-3}$ ) [Suppl. Tab. 14]. Of the six CpGs annotated to *CHRM1*,  
255 with two of them significant (cg06289725: MM=0.86, P=0.029; cg00987015: MM=0.63,  
256  $P=9.0 \times 10^{-3}$ , Suppl. Tab. 9) were also present in the ME4:yellow module, enriched for muscle  
257 system process and synaptic transmission (Suppl. Tab. 14). The ME13:orange module was  
258 enriched for 16 biological processes including the top terms stem cell differentiation (FDR  
259 adjusted  $P = 9.26 \times 10^{-3}$ ) enriched in transcriptional repressor *REST* and positive regulation of  
260 protein kinase B signaling (FDR adjusted  $P = 9.26 \times 10^{-3}$ ). Interestingly, most Reactome pathway  
261 terms included negative regulation of the PI3K/AKT (phosphatidylinositol 3-kinase/Protein  
262 Kinase B) network (FDR adjusted  $P = 1.41 \times 10^{-2}$ ) and Wnt signaling pathway (FDR adjusted  $P =$   
263  $1.60 \times 10^{-2}$ ) was also a part of the ME13:orange module (Suppl. Tab. 15, **Figure 4**). The  
264 ME18:saddlebrown module was mainly enriched for peptidyl-tyrosine autophosphorylation (FDR  
265 adjusted  $P = 8.46 \times 10^{-3}$ ), L1CAM interactions (FDR adjusted  $P = 1.19 \times 10^{-2}$ ) and synaptic  
266 transmission/signaling (FDR adjusted  $P = 1.82 \times 10^{-2}$ ) and included *CHRM1* (Suppl. Tab. 16,  
267 Suppl. Fig. 15).

268

269 ***Adult lung network projection onto fetal lung methylation***

270 To assess the robustness of our findings, we repeated our analyses projecting the adult lung  
271 methylation network structure on the fetal lung methylation. We identified 55 co-methylation  
272 modules with sizes ranging from 35 to 36,455 CpGs. A total of 287,671 CpGs were assigned to a  
273 module (Suppl. Fig. 17A). We used the adult lung methylation module structure as the reference  
274 network for the fetal lung methylation data (Suppl. Fig. 17A-B). Twenty-one modules were  
275 associated with COPD (Suppl. Fig. 17A). Although, none of the module eigengenes reached  
276 statistical significance for association with IUS-exposure, 25 modules showed striking significant  
277 associations with fetal age (Suppl. Fig. 17B). Eleven modules associated with COPD were  
278 associated with fetal age/development: ME24:midnightblue (n=5,564), ME52:salmon4 (n=39),  
279 ME3:brown (n=30,098), ME14:cyan (n=6,432), ME33:darkolivegreen (n=510), ME12:plum1  
280 (n=260), ME38:tan (n=7,281), ME32:violet (n=605), ME39:orangered4 (n=211), ME21:purple  
281 (n=10,256) and ME43:orange (n=1,538) (Suppl. Fig. 17A). Three of those: ME52:salmon4  
282 (Zsummary=12.79), ME14:cyan (Zsummary=11.82), and ME32:violet (Zsummary=13.51), were  
283 also highly preserved (Suppl. Fig. 18, Suppl. Tab. 17); the remaining eleven showed weak-to-  
284 moderate preservation (Suppl. Tab. 17). The preserved modules were enriched in developmental  
285 processes such as anatomical structure morphogenesis and nervous system development.  
286 Enriched pathways included EGFR tyrosine kinase inhibitor resistance, ERBB signaling down-  
287 regulation and PI3K/AKT. This analysis further supports that adult lung network perturbations  
288 might have origins in fetal development associated epigenetic perturbations, especially with  
289 enrichment in the PI3K/AKT signaling pathway.

290

291 **Supplementary Figures**

292

293 **Suppl. Fig. 1.** Multidimensional scaling plot (MDS) plot showing global clustering of CpGs in  
294 smoke-exposed vs. unexposed samples in fetal lung data (blue: unexposed, red: exposed) a)  
295 before covariate adjustment b) Constrained analysis of principal coordinates adjusted for age, sex  
296 and sample plate and sentrix position as technical covariates highlights group clusters.  
297

298

299

300

301 **Suppl. Fig. 2.** Effect size and coverage of CpGs in fetal lung data **A.** Volcano Plot showing the  
302 effect size (beta difference) on the x-axis and the significance on the y-axis. Hyper-methylated  
303 CpGs are on the positive scale and hypo-methylated CpGs are on the negative scale of the x-axis  
304 **B.** Manhattan plot shows the distribution of CpGs across all chromosomes at FDR < 0.05 (green  
305 line) and nominally significant CpGs (P<0.05, n=10,149, blue line).

 323

324 **Suppl. Fig. 4.** Enrichment of nominally significant CpGs ( $p < 0.05$ ) in CpGs shelves and shores  
 325 for fetal lung data. 6,315 of 10,149 nominally significant CpGs had CGI annotations, which were  
 326 significantly enriched in North shelves (2%,  $P = 8.4 \times 10^{-3}$ ), North shores (2.67%,  $P = 9.6 \times 10^{-27}$ ) and  
 327 South shores (2.47%,  $P = 8.3 \times 10^{-10}$ ) against the CpGs on the 450K-array platform. P-value for  
 328 north shores has been rounded in the plot.  
 329

330  
 331  
 332 **Suppl. Fig. 5.** Permutation test for the 255 CpGs identified in fetal lung dataset in same direction  
 333 of effect with the 535 robust CpGs from the LT-COPD study [1]. Five hundred thirty five CpGs  
 334 were randomly selected from the fetal lung data and investigated for numbers in same direction.  
 335 This process was repeated 1000 times to estimate the mean number of overlapping CpGs and the  
 336 empirical p-value as the number of permutations with an overlap larger or equal than the  
 337 observed overlap. The observed overlap was significantly larger than expected by chance in all  
 338 1000 permutations represented by the histogram and the red line (Permutation based p-value =  
 339  $9.9 \times 10^{-4}$ )  
 340

**Suppl. Fig. 6.** Differentially methylated CpGs in *CHRM1*. **A.** Regional plot for *CHRM1* highlighting the two statistically significant and promoter flanking CpGs: cg00987015 (chromosome 11:62,688,751,  $p=9.0 \times 10^{-3}$ ), cg06289725 (chromosome 11:62,689,081,  $p=0.029$ ) strongly enriched in DNase hypersensitivity sites (DHS). **B.** Sushi violin plot showing the 15 CpGs annotated to *CHRM1* gene. Only two of them were statistically significant (also shown in a.) and hyper-methylated in smoke-exposed (dark colored) versus unexposed (light colored) fetal lung samples, located in 5'UTR and transcription start site (TSS) respectively. However, there was a trend of global hypo-methylation around that region.

352  
353

355  
356

357

358 **Suppl. Fig. 7.** Module-trait association heatmaps highlighting fetal origins for COPD at network  
 359 for all 103 modules **a)** Association of modules in the fetal lung network with the traits of interest  
 360 **b)** Association of COPD traits of interest projected on to fetal lung module network as reference.  
 361 The Y-axis shows the modules represented by their colors, followed by module eigengene label  
 362 and the number of CpGs in that respective module. The panels highlight modules associated with  
 363 IUS-exposure, gestational age, COPD and lung function phenotypes. The blue and yellow colors  
 364 in the boxes represent the scale for significance (nominal  $P < 0.05$ ) with blue being not significant  
 365 and yellow being highly significant. The mean beta effect estimate per module corresponding to  
 366 the trait is shown below in parentheses (Suppl. Tab. 5 and 7).

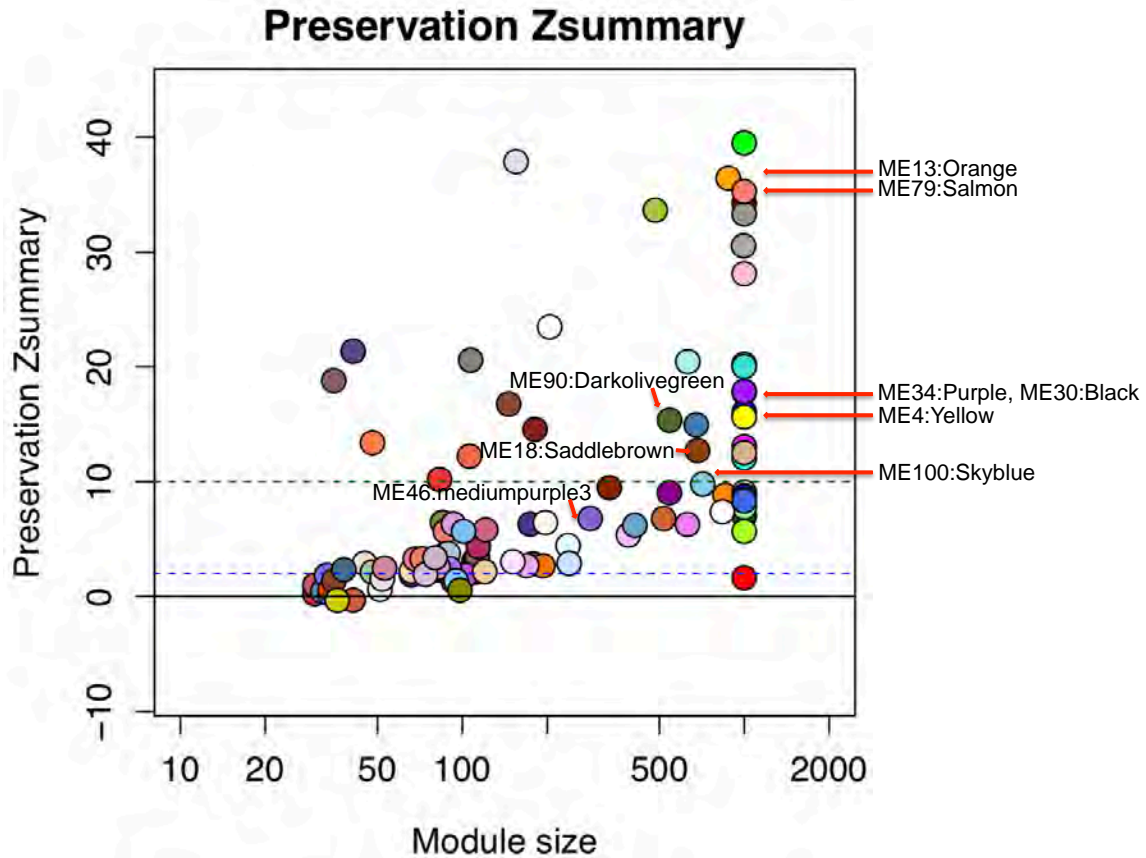

367 cat\_exposure: IUS-exposure (exposed versus unexposed), cont\_exposure: IUS-exposure  
 368 (continuous cotinine variable). COPD\_ctrl: COPD (cases versus controls), FEV<sub>1</sub>: forced  
 369 expiratory volume in 1 sec, FVC: forced vital capacity, FEV<sub>1</sub>/FVC ratio, LAA950: measure for  
 370 emphysema, perc15 and monthsquit: months since quitting

371 Missing Data: FEV<sub>1</sub> and FVC were missing for 13 subjects, LAA950 and perc15 were missing  
 372 for 55 subjects and monthsquit was missing for one subject. Subjects with missing data were  
 373 removed prior to running models for these predictors.

376 **Suppl. Fig. 8.** Preservation between fetal lung (reference) and adult lung data (test). The figure  
 377 displays module size on x-axis (cut-off set to n=2000) and preservation Zsummary on the y-axis  
 378 (permutation based measure of preservation) to convey the range of preservation Z-summary  
 379 statistics for the highly preserved modules compared to other modules. The preservation plot  
 380 shows that several modules are either highly or moderately preserved between both fetal lung and  
 381 adult lung data, however nine modules were exclusively associated with IUS-exposure, age and  
 382 COPD/lung function as highlighted in the figure and in the paper.

**Suppl. Fig. 9.** Correlation between the ME90:darkolivegreen methylation eigengene and traits of  
 interest A. Eigengene values of the ME90:darkolivegreen module were relatively increased and  
 B. positively correlated with cotinine values in IUS-exposed fetal lung samples compared to  
 unexposed samples. For exposure, 0 corresponds to unexposed samples whereas 1 corresponds to  
 IUS-exposed samples C. In LT-COPD dataset, highest positive eigengene values of the  
 ME90:darkolivegreen module were relatively associated with COPD cases and D. significantly  
 correlated with lower FEV<sub>1</sub> values and E. pack-years compared to healthy smoker controls. The  
 x-axis in plots A and C represent the sample sorted by their eigengene values.

396

401

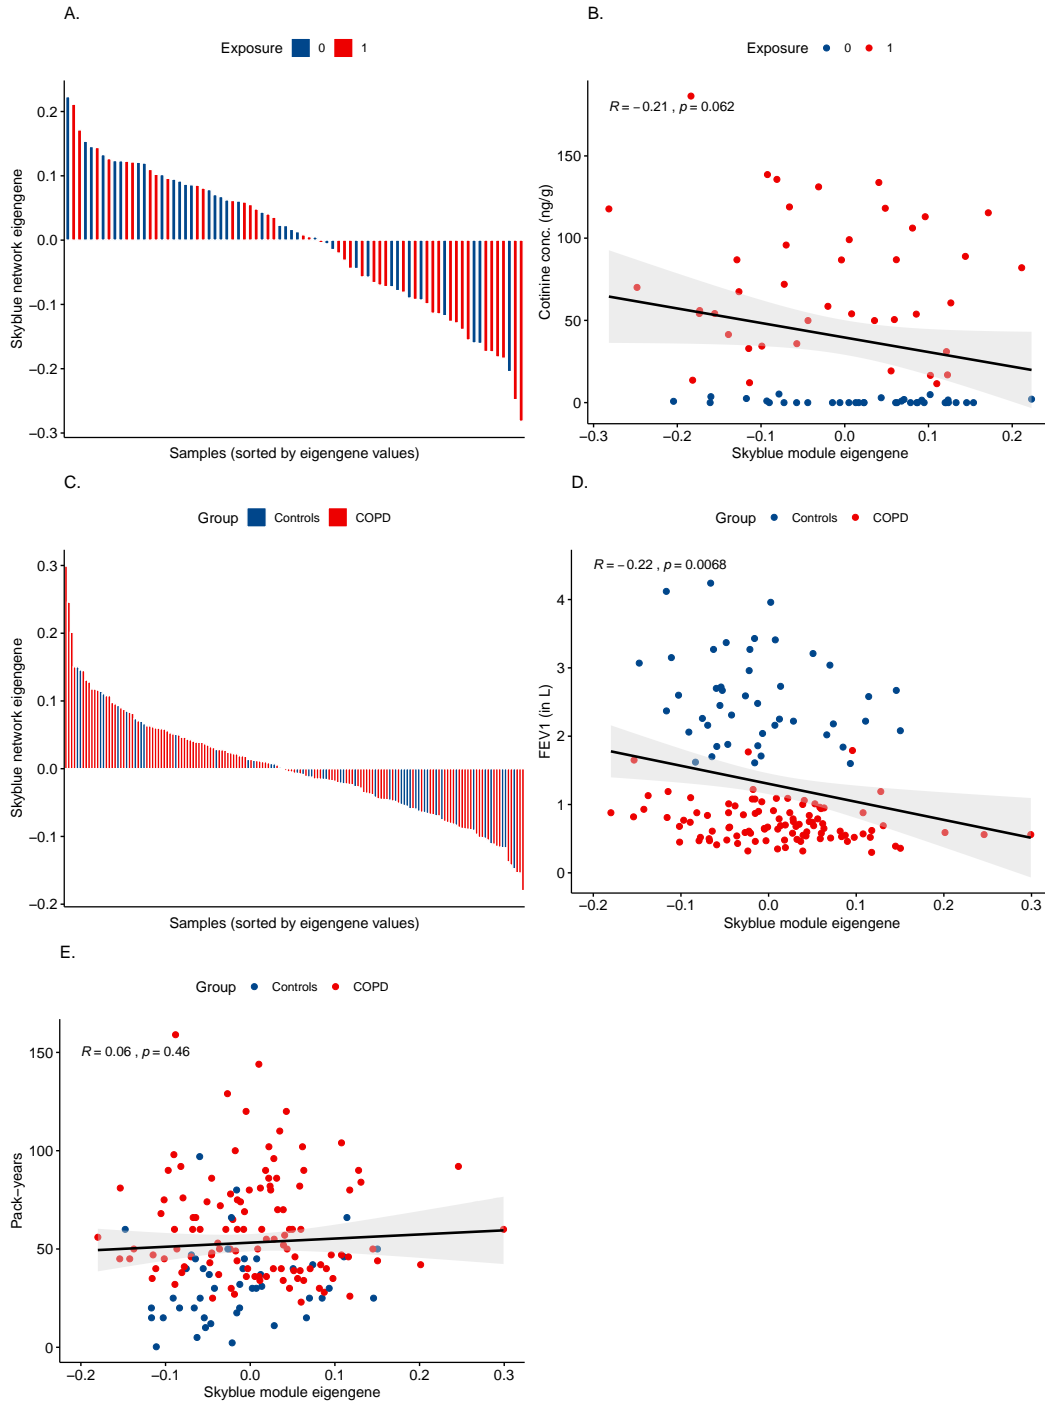

**Suppl. Fig. 10.** Correlation plots between the ME34:purple methylation eigengene and traits of interest. A. Lowest eigengene values of the ME34:purple module were seen for exposed samples

402 B. and associated with higher cotinine levels in exposed samples. For exposure, 0 corresponds to  
 403 unexposed samples whereas 1 corresponds to IUS-exposed samples C. In LT-COPD dataset,  
 404 highest positive eigengene values of the ME34:purple module were associated with COPD cases  
 405 and D. significantly correlated with lower FEV<sub>1</sub> values in COPD adults compared to controls and  
 406 E. No association was observed between ME34:purple module eigengene and pack-years. The x-  
 407 axis in plots A and C represent the sample sorted by their eigengene values.  
 408

409 **Suppl. Fig. 11.** Correlation plots between the ME100:skyblue methylation eigengene and traits of  
 410 interest. A. Eigengene values of the ME100:skyblue module were lower and B. correlated with  
 411

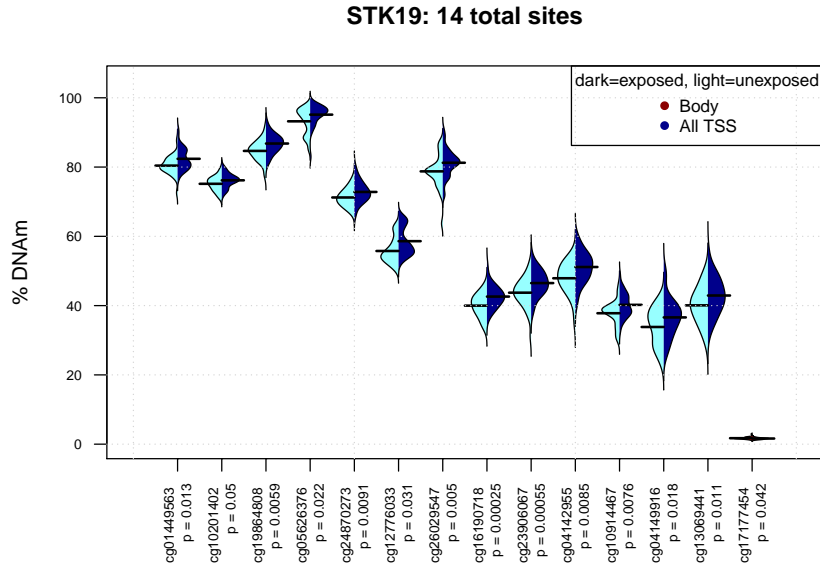

412 higher cotinine levels in IUS-exposed fetal lung samples compared to unexposed samples. For  
 413 exposure, 0 corresponds to unexposed samples whereas 1 corresponds to IUS-exposed samples C.  
 414 In LT-COPD dataset, highest positive eigengene associations of the ME100:skyblue module were  
 415 observed in COPD cases D. that were significantly correlated with lower FEV<sub>1</sub> values E. No  
 416 association was observed between ME100:skyblue module eigengene and pack-years. The x-axis  
 417 in plots A and C represent the sample sorted by their eigengene values.  
 418

419  
 420 **Suppl. Fig. 12.** Violin plot showing the 14 significant and hyper-methylated CpGs in smoke-  
 421 exposed (dark colored) vs. unexposed (light colored) fetal lung samples (data pulled from Suppl.

422 Tab.2); 13 of those located around transcription start site (TSS) of *STK19* gene. Seven of those 14  
 423 CpGs (Suppl. Tab. 8) were also present within the mediumpurple3, ME46:mediumpurple3  
 424 module.

**Suppl. Fig. 13.** Gene enrichment and pathway analysis for ME90:darkolivegreen module primarily associated with regulation of telomerase RNA localization to cajal body (Suppl. Tab. 11). Cajal bodies are usually found in proliferative cells like embryonic/tumor cells, or metabolically active cells like neurons. Node size corresponds to the number of genes in the enriched term. Node color corresponds to the significance of the term. Edge size corresponds to the number of genes that overlap between two connected terms/gene-sets.

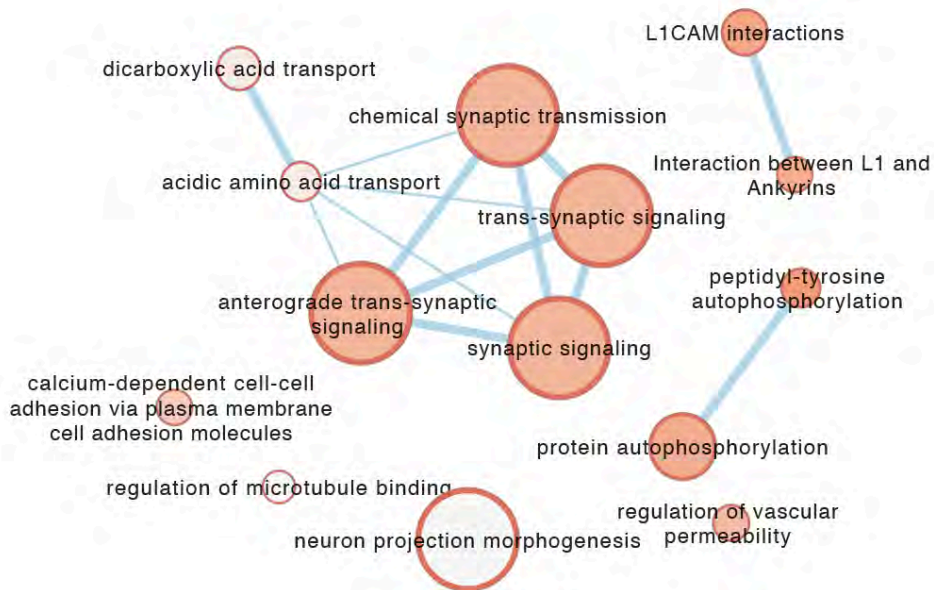

436  
 437  
 438  
 439  
 440  
 441

**Suppl. Fig. 14.** Gene enrichment and pathway analysis for ME100:skyblue module, enriched for all reactome pathways (Suppl. Tab. 11) including cell-cell communication (10 genes, FDR

442 adjusted  $P = 9.45 \times 10^{-3}$ ), cell junction organization (8 genes, FDR adjusted  $P = 0.01$ ), *ERBB4*  
 443 signaling (5 genes, FDR adjusted  $P = 0.04$ ). Node size corresponds to the number of genes in the  
 444 enriched term. Node color corresponds to the significance of the term. Edge size corresponds to  
 445 the number of genes that overlap between two connected terms/gene-sets.  
 446

447  
 448  
 449  
 450 **Suppl. Fig. 15.** Gene enrichment and pathway analysis for ME18:saddlebrown module (Suppl.  
 451 Tab. 16) Node size corresponds to the number of genes in the enriched term. Node color  
 452 corresponds to the significance of the term. Edge size corresponds to the number of genes that  
 453 overlap between two connected terms/gene-sets.  
 454  
 455

456  
 457  
 458  
 459 **Suppl. Fig. 16.** Gene enrichment and pathway analysis for ME46:mediumpurple3 module. The  
 460 module is enriched for viral biological processes (FDR adjusted  $P = 6.58 \times 10^{-7}$ ), ribonucleoprotein  
 461 biogenesis (FDR adjusted  $P = 4.09 \times 10^{-5}$ ), DNA repair (FDR adjusted  $P = 8.44 \times 10^{-4}$ ) and top

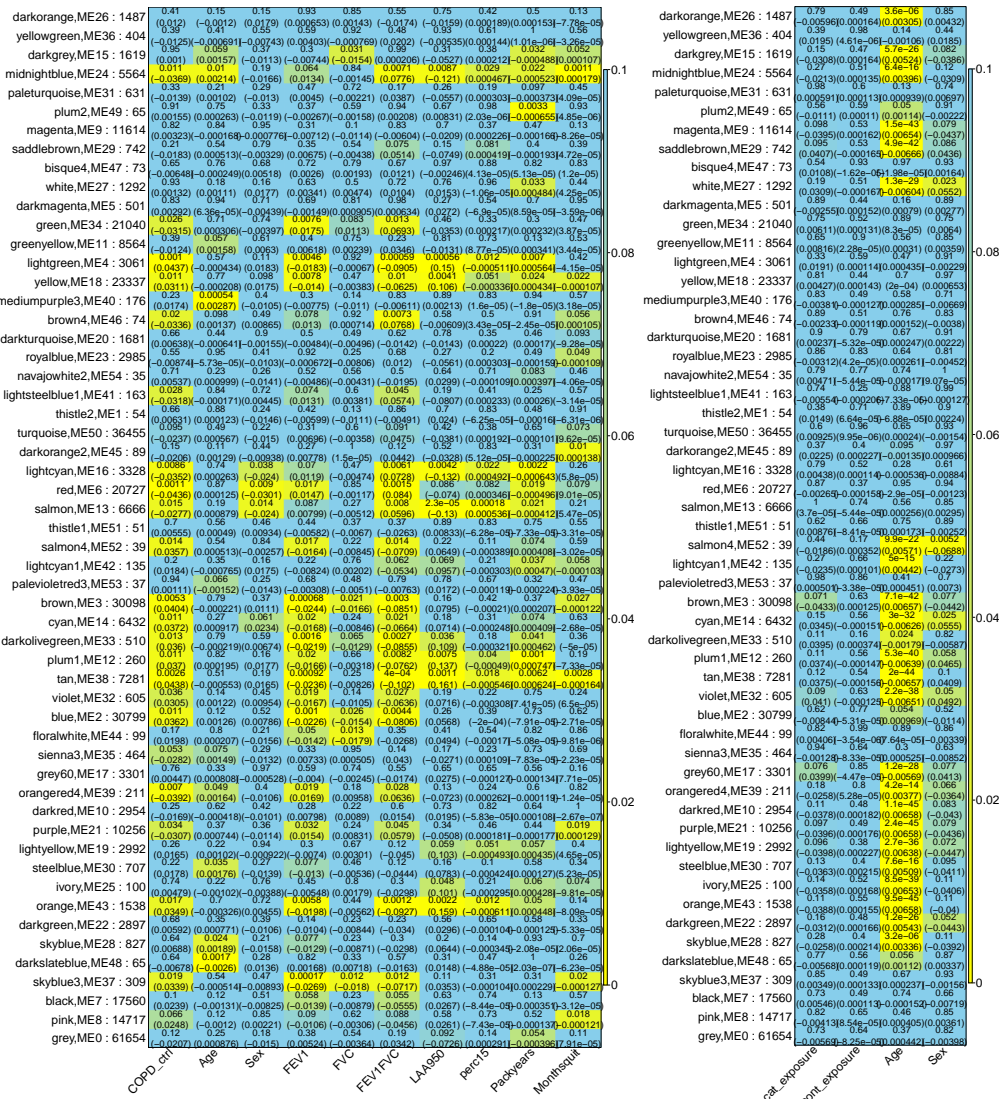

462 pathway included PIP3 activated PI3K/AKT signaling (FDR adjusted  $P = 1.81 \times 10^{-3}$ ). Due to the  
 463 complexity of network, for this analysis, we considered only one parent node and reduced the  
 464 connections to the terms not having an exact overlap of genes defined by the edge weight equal to  
 465 1. The analysis displayed sub networks including pathways for apoptotic signaling, response to  
 466 oxidative stress, autophagy, signaling cascades connecting PI3K/AKT network, MAPK signaling  
 467 and signaling by WNT and neutrophil mediated immune response (Suppl. Tab. 10). Node size  
 468 corresponds to the number of genes in the enriched term. Node color corresponds to the  
 469 significance of the term. Edge size corresponds to the number of genes that overlap between two  
 470 connected terms/gene-sets.  
 471

472  
 473  
 474 **Suppl. Fig. 17.** Module-trait heatmaps highlight COPD disease recapitulates fetal development **a)**  
 475 Association of modules in the COPD network with the traits of interest **b)** Association of traits of  
 476 interest in fetal lung dataset projected on to COPD module network as reference. The Y-axis  
 477 shows the modules represented by their colors, followed by module eigengene label and the

478 number of CpGs in that respective module. The panels highlight modules associated with IUS-  
 479 exposure, gestational age, COPD and lung function phenotypes. The blue and yellow colors in the  
 480 boxes represent the scale for significance (nominal P<0.05) with blue being not significant and  
 481 yellow being highly significant. The mean beta effect estimate per module corresponding to the  
 482 trait is shown below in parentheses. Most modules were associated with fetal age, lung function  
 483 and COPD but none associated with both IUS-exposure and COPD.

485 cat\_exposure: IUS-exposure (exposed vs. unexposed), cont\_exposure: IUS-exposure (continuous  
 486 cotinine). COPD\_ctrl: COPD (cases vs. controls), FEV<sub>1</sub>: forced expiratory volume in 1 sec, FVC:  
 487 forced vital capacity, FEV<sub>1</sub>/FVC ratio, LAA950: measure for emphysema, perc15 and  
 488 monthsquit: months since quitting
